

LHCb status report

LHCC open session

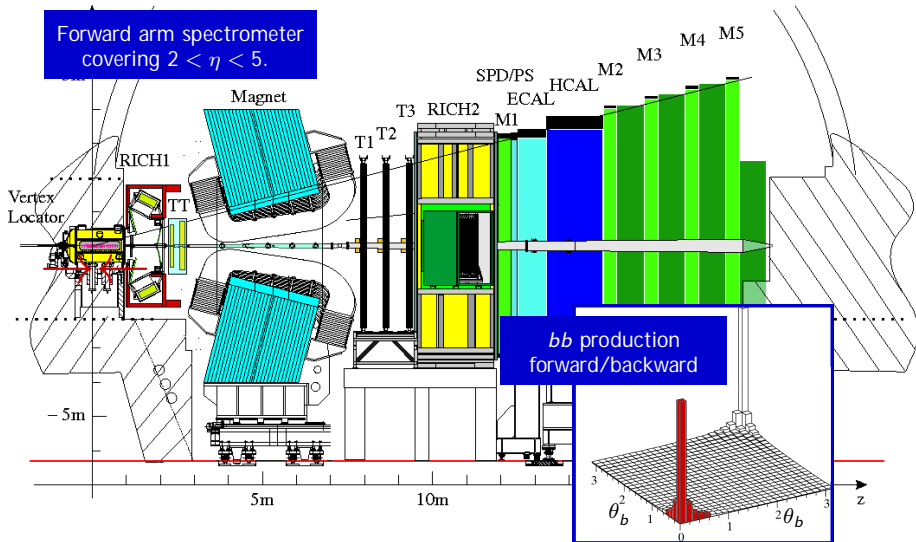

T. Blake on behalf of the LHCb collaboration

March 2013

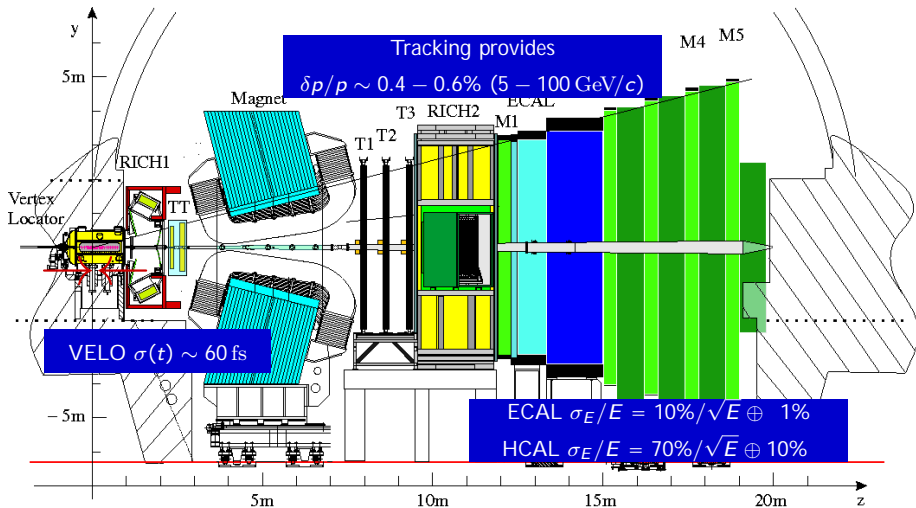

1. Data taking, data processing and computing.
2. Tour of recent LHCb results.
3. Proton-ion data taking.
4. The LHCb upgrade.

The LHCb detector

The LHCb detector

Particle ID: $\varepsilon(K \rightarrow K) \sim 95\%$ for $\varepsilon(\pi \rightarrow K) \sim 5\%$, $\varepsilon(\mu \rightarrow \mu) \sim 97\%$ for $\varepsilon(\pi \rightarrow \mu) \sim 1\%$.

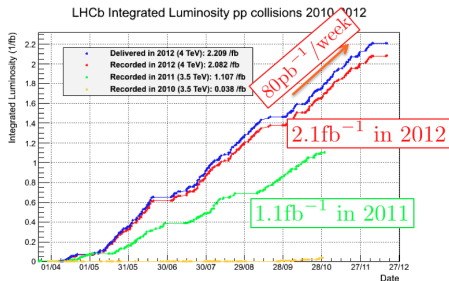

Detector aging

- CALO: Perform regular gain calibrations to account for aging of the detector.
- OT: Small decrease in gain but no strong evidence of aging of the OT straw tubes.
- VELO: Depletion voltages are evolving in good agreement with expectations (replacement detector prepared).

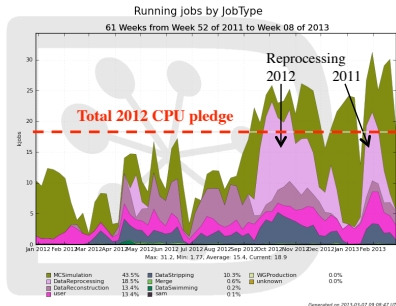

Data taking during 2012

- LHCb collected an additional 2.1 fb^{-1} of integrated luminosity at $\sqrt{s} = 8 \text{ TeV}$ in 2012.
- Average data taking efficiency $\sim 95\%$.
- Further, gain statistics for many analyses due to the increased $b\bar{b}$ and $c\bar{c}$ cross-sections ($\sim 8=7$) at 8 TeV .
- Reminder:
 - $b\bar{b} = 75 \pm 14 \text{ b}$ at $\sqrt{s} = 7 \text{ TeV}$ [LHCb-PAPER-2010-002]
 - $c\bar{c} = 1419 \pm 134 \text{ b}$ at $\sqrt{s} = 7 \text{ TeV}$ [LHCb-PAPER-2012-041]in the LHCb acceptance.

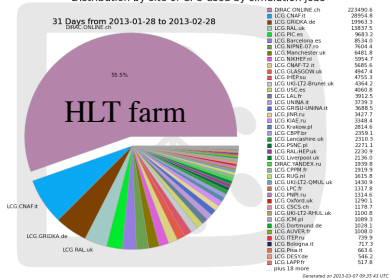

Data re-processing and simulation

- Re-processing of 2011 and 2012 data (Reco 14) with latest alignment and calibration is now complete → consistent 3 fb^{-1} dataset.
 - Reco 14 will be used for all new analyses during LS1.

Distribution by site of CPU used by simulation jobs

- The LHCb HLT farm has also been fully commissioned for offline use.
 - Already deployed during February (in parallel to proton-ion data taking) for MC simulation → 55% of simulation CPU came from the HLT farm.

Recent LHCb results

Submitted papers (since the last LHCC open session)

In total, LHCb has now submitted **100** papers for publication.

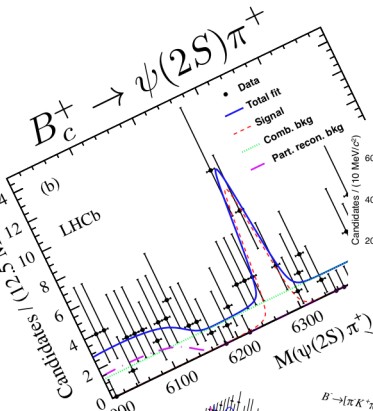

Another 23 will be submitted shortly.

We have also prepared 105 conference reports.

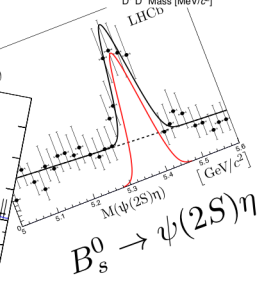

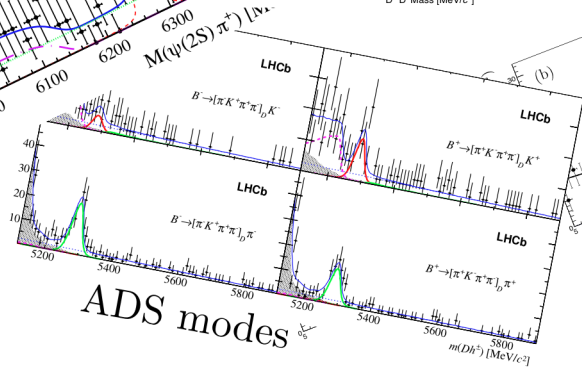

- Since the last LHCC open presentation (December 2012) we have submitted papers on:
 - \Observation of the decay $B_c^+ \rightarrow \psi(2S)\pi^+$ " [CERN-PH-EP-2013-028]
 - \Measurements of the $\frac{0}{b} \rightarrow J/\psi$ decay amplitudes and the $\frac{0}{b}$ polarisation in pp collisions at $\sqrt{s} = 7$ TeV" [CERN-PH-EP-2013-020]
 - \Observation of the $B_s^0 \rightarrow \psi(2S)\eta$ and $B_{(s)}^0 \rightarrow \psi(2S)\pi^+\pi^-$ decays" [CERN-PH-EP-2013-024]
 - \Determination of the $X(3872)$ meson quantum numbers" [CERN-PH-EP-2013-017]
 - \Prompt charm production in pp collisions at $\sqrt{s} = 7$ TeV" [CERN-PH-EP-2013-009]
 - \Amplitude analysis and the branching fraction measurement of $\bar{B}_s^0 \rightarrow J/\psi K^+ K^-$ " [CERN-PH-EP-2013-008]
 - \Search for the decay $B_s^0 \rightarrow D^{*\pm}\pi^\pm$ " [LHCb-PAPER-2012-056]

Submitted papers (since the last LHCC open session)

- "Measurement of the Λ_b^0 , $\bar{\Lambda}_b^0$ and Σ_b^- baryon masses" [CERN-PH-EP-2013-013]
- "Exclusive J/ψ and $\psi(2S)$ production in pp collisions at $\sqrt{s} = 7$ TeV" [CERN-PH-EP-2013-005]
- "Analysis of the resonant components in $\bar{B}^0 \rightarrow J/\psi \pi^+ \pi^-$ " [CERN-PH-EP-2013-004]
- "Measurement of the fragmentation fraction ratio f_s/f_d and its dependence on B meson kinematics" [CERN-PH-EP-2013-006]
- "Measurement of CP observables in $B^0 \rightarrow DK^{*0}$ with $D \rightarrow K^+ K^-$ " [CERN-PH-EP-2012-362]
- "Measurement of the cross-section for $Z^0 \rightarrow e^+ e^-$ production in pp collisions at $\sqrt{s} = 7$ TeV" [CERN-PH-EP-2012-363]
- "Measurement of the forward energy flow in pp collisions at $\sqrt{s} = 7$ TeV" [CERN-PH-EP-2012-346]
- "Measurement of J/ψ production in pp collisions at $\sqrt{s} = 2.76$ TeV" [CERN-PH-EP-2012-349]
- "Search for direct CP violation in $D^0 \rightarrow h^+ h^-$ modes using semileptonic B decays" [LHCb-PAPER-2013-003]
- "Search for the rare decays $B_{(s)}^0 \rightarrow \mu^+ \mu^- \mu^+ \mu^-$ decays" [LHCb-PAPER-2012-049]
- "First observation of $\bar{B}_s^0 \rightarrow D^+ D^-$, $D_s^+ D_s^-$ and $D^0 \bar{D}^0$ decays" [LHCb-PAPER-2012-050]

$B_s^0 \rightarrow D^+ D^-$ and $B_s^0 \rightarrow D^0 \bar{D}^0$

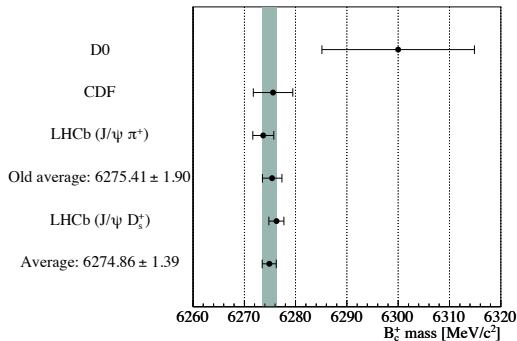

First observation of the decay $B_c^+ \rightarrow D_s^{(*)+} J/\psi$

- [LHCb-PAPER-2013-010] using the full 3 fb^{-1} dataset
- Allows for a precise determination of the B_c^+ mass:

$$m_{B_c^+} = 6276.28 \pm 1.44 \pm 0.36 \text{ MeV}/c^2$$

Determining the B_c^+ mass

- The new result is more precise than the old world average, $m_{B_c^+} = 6275.41 \pm 1.90$, and is statistically dominated.

B_S^0 mixing and mixing induced CP violation

[LHCb-PAPER-2013-006]

[LHCb-PAPER-2013-002]

[LHCb-PAPER-2013-007]

- Mass eigenstates \neq flavour eigenstates.
- Oscillation frequency $\propto \Delta m_s = m_H - m_L$.

- Ignoring decay time acceptance and detector resolution, the decay time distribution of tagged candidates to a flavour specific final state is:

$$P(t) \propto e^{-t} \left[\cosh \frac{\Delta\Gamma_s}{2} t \pm \mathcal{D} \cos(\Delta m_s t) \right]$$

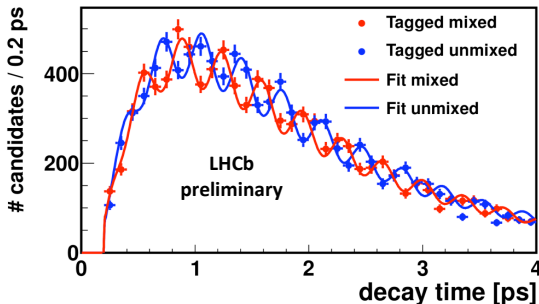

where \mathcal{D} is the flavour tagging dilution.

$B_s^0 - \bar{B}_s^0$ oscillation frequency

- Mixing analysis performed using 1 fb^{-1} of integrated luminosity using flavour specific $B_s^0 \rightarrow D_s^- +$ and $\bar{B}_s^0 \rightarrow D_s^+ -$ final states.
- Use opposite side + same-side kaon taggers to tag the initial flavour of the B_s^0/\bar{B}_s^0 (effective tagging power " $\mathcal{D}^2 \sim 3:1\%$ ").

- Excellent proper time resolution in LHCb

→ can resolve $B_s^0 - \bar{B}_s^0$ oscillations.

$$\Delta m_s = 17.768 \pm 0.023(\text{stat.}) \pm 0.006(\text{syst.}) \text{ ps}^{-1}$$

c.f. $17.77 \pm 0.10 \pm 0.07 \text{ ps}^{-1}$ @ CDF [PRL 97 242003 (2006)]

Mixing induced CP violation in B_s^0 -system

- Interference between mixing and decay gives rise to a CP phase: $\phi_s = \delta_m - 2\delta_d$.
- For $B_s^0 \rightarrow J/\psi$, $\delta_d = -2\arg(V_{cs}V_{cb}^*) \approx 0$ and

$$\phi_s^{\text{SM}} = -2\arg\left(\frac{V_{ts}V_{tb}^*}{V_{cs}V_{cb}^*}\right) = -0.036 \pm 0.002 \text{ rad}$$

Charles et al. [[Phys. Rev. D84 \(2011\) 033005](#)]

- Mixing phase, δ_m , from $\Delta B = 2$ box diagram.
- Sensitive to NP contributions.

Mixing induced CP violation in B_s^0 -system

- Can also look at $B_s^0 \rightarrow J/\psi \phi$ decays (gluonic penguin).
- Loop suppressed $\rightarrow 880 \pm 31$ candidates. Can also receive NP contribution to the decay.
- In the SM, partial cancellation between m and $d \rightarrow$ expect $\frac{A_m}{A_d} \sim 0$.

- In both cases, perform a time dependent, flavour tagged, angular analysis to separate the CP-odd and CP-even final states.

CP even, CP odd, S-wave

CP even, CP odd, S-wave

Mixing induced CP violation in $B_s^0 \rightarrow J/\psi \phi$

- Several improvements in the analysis from the preliminary result:

1. Added same-side kaon tagging, " $\mathcal{D}^2 = (0.89 \pm 0.17)\%$."
2. Simultaneous fit in six bins of $m_{K^+K^-}$. The strong phase dependence across the pole-mass is used to resolve the sign of $\Delta\Gamma_s$.
3. Allow for CP violation in the decay,

$$|\bar{A}_f| = \left| \frac{q \bar{A}_f}{p A_f} \right| = 0.94 \pm 0.03 \pm 0.02:$$

- Dominant source of systematic uncertainty arises from the angular acceptance (limited MC statistics).

Mixing induced CP violation in $B_s^0 \rightarrow \phi\phi$

- Small dataset \rightarrow Feldman Cousins (pseudo-experiments) are used to provide the correct coverage.
- The result is statistically limited.

ϕ_s in interval $[-2.46; -0.76]$ rad at 68% CL.

- p-value of $\phi_s = 0$ is 16%.
- The dominant sources of systematic uncertainty arise from:
 - the description of the decay time acceptance;
 - the knowledge of the S-wave contamination from $B_s^0 \rightarrow f^0$ and $B_s^0 \rightarrow f^0 f^0$.
- Interesting analysis to pursue with larger datasets (NB: we have an additional 2 fb^{-1} on tape).

Mixing induced CP violation in the B_s^0 -system

- HFAG Fall 2012 combination of results from CDF & D0, the old LHCb preliminary result and an untagged analysis from ATLAS.

LHC Seminar

SPEAKER:

Jeroen Van Tilburg (Ruprecht-Karls-Universitaet
Heidelberg (DE))

TITLE:

**New results on CP violation in the charm
sector**

DATE:

Tue 12/03/2013 11:00

PLACE:

Council Chamber

CP violation in the charm sector

[[LHCB-PAPER-2013-003](#)], [[LHCB-CONF-2013-003](#)]

Link to seminar: <http://indico.cern.ch/conferenceDisplay.py?confId=240082>

Direct CP violation in charm

- CP violation is well established in the K and B systems.
- Not yet established in the charm sector:
 - CP violation in singly-Cabibbo suppressed charm decays is expected to be small $\lesssim 0.1\%$ (but is difficult to calculate).
- With 0.6 fb^{-1} LHCb measured $\Delta A_{CP} = (-0.82 \pm 0.21 \pm 0.11)\%$ between $K^+ K^-$ and $^+ ^-$ final states.
- HFAG world average shows 4.6 evidence for CP violation in $D \rightarrow h^+ h^-$ decays. For charm system $\Delta A_{CP} \approx \Delta a_{CP}^{\text{dir}}$.
- Triggered a detailed discussion in the theory community on SM predictions and possible NP interpretations.

Measuring ΔA_{CP}

- To determine the CP asymmetry of $D \rightarrow h^+ h^-$ decays need to tag the flavour of the D^0/\bar{D}^0 :

- Use the charge of s in $D^{*+} \rightarrow D^0 s^+$.

NEW Use D 's from semileptonic B decays and use the \pm charge.

- Raw CP asymmetry $A_{RAW}(h^+ h^-) \approx A_{CP} + A_D + A_P$ depends on the D^{*+}/D^{*-} ($B=\bar{B}$) production asymmetry and the \pm (\mp) detection asymmetry. Can cancel A_P and A_D to first order by taking:

$$\Delta A_{CP} = A_{RAW}(K^+ K^-) - A_{RAW}(^+ ^-) \approx A_{CP}(K^+ K^-) - A_{CP}(^+ ^-)$$

NB $A_{CP}(K^+ K^-)$ and $A_{CP}(^+ ^-)$ expected to have opposite sign in SM.

Updating the $D^{*\pm}$ tagged analysis to 1 fb^{-1}

- Several analysis improvements:
 - Added an additional 0.4 fb^{-1} .
 - Improved alignment and calibration used for the full dataset.
 - Improved $m = m_{h^+h^-} + - m_{h^+h^-} - m +$ mass resolution, by introducing a PV constraint in the vertex fit.

→ Updated value of:

$$\Delta A_{CP} = (-0.34 \pm 0.15 \pm 0.10)\% \quad (\text{Preliminary})$$

- Statistically compatible with the previous result.
- The dominant sources of systematic uncertainty arise from the:
 - treatment of possible peaking backgrounds (0.04%);
 - dependence of ΔA_{CP} on the impact parameter of s (0.08%).

ΔA_{CP} using semileptonic tags

- Estimate ΔA_{CP} by performing a simultaneous fit to the $h^+ h^-$ mass for D^0 and \bar{D}^0 tagged events.
 - Candidates are re-weighted to account for kinematic differences between $D \rightarrow K^+ K^-$ and $D \rightarrow \pi^+ \pi^-$.
 - Average results from two LHCb magnet polarities to further cancel detector asymmetries.

ΔA_{CP} using semileptonic tags

- Signal samples of 560 k $D \rightarrow K^+ K^-$ and 220 k $D \rightarrow \pi^+ \pi^-$ decays.
- For the semileptonic tagged analysis:

$$\Delta A_{CP} = (+0.49 \pm 0.30 \pm 0.14)\%$$

- The dominant sources of systematic uncertainty come from the:
 - treatment of low lifetime backgrounds in $D \rightarrow \pi^+ \pi^-$ (0.11%);
 - kinematic re-weighting (0.05%);
 - modelling of the D line-shape (0.05%).

- Measurements compatible at 2:2 level:

$$D^{*+} \text{ tag } \Delta A_{CP} = (-0.34 \pm 0.15 \pm 0.10)\% \text{ (preliminary)}$$

$$\text{Semileptonic tag } \Delta A_{CP} = (+0.49 \pm 0.30 \pm 0.14)\%$$

NB Naive average, ignores $a_{CP}^{\text{ind.}}$ and possible correlations between experimental uncertainties.

→ Initial evidence for CP violation in the charm sector is not confirmed.

Exotic charmonium states

[LHCb-PAPER-2013-001]

$X(3872)$ meson quantum numbers

- $X(3872)$ is an exotic charmonium state first observed by Belle [PRL 91 (2003)] in $B^+ \rightarrow K^+ \pi^+ J/\psi$ decays.
- $X(3872)$ also observed to decay as $X(3872) \rightarrow J/\psi$ by BaBar and Belle ($\rightarrow C = +1$)
- CDF excluded all J^{PC} except 1^{++} and 2^{-+} [PRL 98 (2007)] using a 3D angular fit.
- Determination of quantum numbers important for interpreting the nature of the $X(3872)$:
 - 1^{++} $\bar{D}^0 D^{*0}$ molecule? Tetra-quark? $c_1(2^3P_1)$?
 - 2^{-+} $c_2(1^1D_2)$?

X(3872) meson quantum numbers

- In 1 fb^{-1} LHCb observes 313 ± 26 $B^+ \rightarrow K^+ X(3872)$ decays, with $X(3872) \rightarrow J/\psi \pi^+ \pi^-$.
- Can distinguish between 1^{++} and 2^{-+} using the 5-dimensional angular distribution of the decay:

$$|\mathcal{M}|^2 = \sum_{\lambda = -1, +1} \left| \sum_{\lambda_{J/\psi}, \lambda} \mathcal{A}_{\lambda_{J/\psi}, \lambda} \right. \times$$

$$\mathcal{D}_{0, \lambda}^J \left(\phi_X, \theta_X, -\phi_X \right) \times$$

$$\mathcal{D}_{\lambda}^1 \left(\phi_{\pi\pi}, \theta_{\pi\pi}, -\phi_{\pi\pi} \right) \times$$

$$\left. \mathcal{D}_{\lambda_{J/\psi}}^1 \left(\phi_{J/\psi}, \theta_{J/\psi}, -\phi_{J/\psi} \right) \right|^2$$

- Background subtracted using the $sPlot$ technique.

$X(3872)$ meson quantum numbers

- Use the likelihood ratio:

$$t = -\log \frac{\mathcal{L}(2^{-+} | \sim)}{\mathcal{L}(1^{++})}$$

as a test statistic.

- $t_{\text{data}} = 99 \rightarrow$ rejects 2^{-+} at 8:4

$J^{PC} = 1^{++}$ consistent with molecular, tetra-quark and $c_1(2^3P_1)$ models
(which leaves room for some of the more exotic interpretations)

Neutral Higgs production

[LHCb-PAPER-2013-009]

Neutral Higgs production

- SM “Higgs” like object has already been seen by ATLAS/CMS.

- At LHCb, search for neutral Higgs decaying to $\gamma^+ \gamma^-$ in the $2 < \eta < 5$ region.

- Search performed with 1 fb^{-1} of integrated luminosity at $\sqrt{s} = 7 \text{ TeV}$.

- ✓ Unique acceptance in the forward-region.

- Sensitive to models where Higgs production in the forward region can be enhanced.

- ✗ Low efficiency to reconstruct both daughters inside the LHCb acceptance.

Neutral Higgs production

- Analysis performed using 5 categories: $-\rightarrow$, $+\rightarrow$, $+\rightarrow$, $-\rightarrow$, $\pm e\bar{\tau}$, $e^\pm\bar{\tau}$, $\pm h$, $e^\pm h$.
- Follow LHC Higgs Cross Section Working Group recommendations for the signal (FeynHiggs, HIGLU, GGH@NNLO, BBH@NNLO). Signal efficiency is data driven.

Backgrounds:

- $Z \rightarrow$ Using theoretical cross-section, shape from MC.
- QCD Semileptonic b - and c -hadron decays.
- EWK Shape from isolation sideband, normalised w.r.t. same-sign.
- EWK Lepton from W^\pm or Z plus track from underlying event.
- $t\bar{t}=WW$ Shape from simulation, normalised w.r.t. same-sign.
- $Z \rightarrow$ Shape from sidebands, normalised to peak.

Neutral Higgs production

- Combining the 5 channels, set model independent upper limits on $\sigma \times \mathcal{B}(\Phi^0 \rightarrow \tau\tau)$ of 9.4 pb (90 GeV= c^2) – 0.3 pb (250 GeV= c^2)

proton-ion running

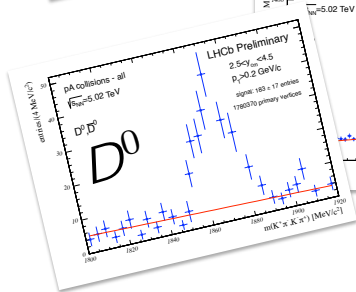

proton-ion running

- LHCb has collected $\sim 2\text{nb}^{-1}$ of proton-ion data:
 - 1.4nb^{-1} of $p\text{Pb}$ and 0.6nb^{-1} of $\text{Pb}p$
- Using SMOG system:
 - injection of Ne gas in interaction region.
 - increased rate of beam-gas interactions for luminosity measurement.

we have also collected samples of minimum bias, fixed-target, $p\text{Ne}$ and PbNe data.

LHCb Integrated Luminosity at p-Pb 4 TeV in 2013

J/

pPb pilot run [LHCb-CONF-2012-034] $\mathcal{L} \sim 0.9$ b⁻¹

LHCb upgrade

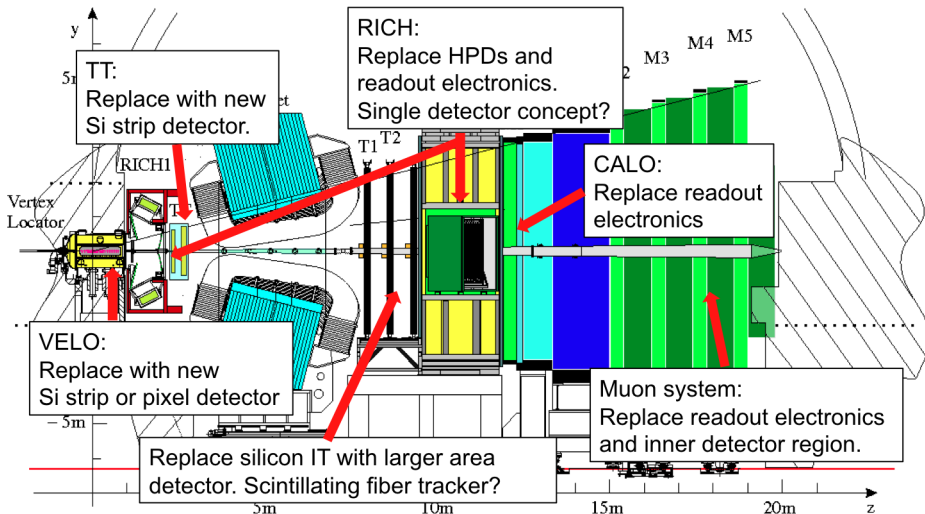

LHCb upgrade

Aim to upgrade the LHCb detector during LS2 (2018), with the goal of reading out the full detector into a software farm at 40 MHz.

- Lol submitted in March 2011.
 - Physics case endorsed by the LHCC.
- Framework TDR submitted in May 2012.
 - Endorsed by the LHCC in September 2012.
- LHCb upgrade approved by Research Board in November 2012.
- We are now starting reviews in the individual sub-detectors (with external referees). These reviews will be completed this year.
- A supporting document on the upgrade physics and trigger is also being prepared.

The LHCb upgrade

First review: scintillating fiber tracker

- A scintillating fiber tracker is a possible replacement for the existing IT and OT .

250 μm scintillating
fibers readout by
128 channel SiPM.

Figure 4: Cross section photograph of a recently built 2.5 m long scintillating-fibre module.

- Review focussed mainly on the radiation tolerance of the fibers/SiPM (see next slide).

Scintillating fiber tracker is viable from point of view of radiation tolerance.

First review: scintillating fiber tracker radiation tolerance

- Known issues with SiPM exposed to neutron fluence.
 - Existing SiPM technologies can keep noise/PDE at acceptable levels with a combination of cooling (-40°C) and shielding.
- Radiation tolerance of the scintillating fibers has also been explored.
 - Fibers have been exposed to 50 fb^{-1} equivalent of protons \rightarrow degradation of the fibers is within the upgrade tolerance (40% closest to the beam line). A sizable fraction of the light loss can be recovered using a mirror at the end of the fiber.

Expected relative light yield before and after irradiation

For more details see the talk in the LHCC upgrade session.

Summary

The LHCb detector performed well during 2012.

proton-ion data taking opens up new possibilities for the LHCb physics programme (unique forward acceptance).

Preparation for the LHCb upgrade is ongoing. Sub-system reviews will take place this year.

Expect many new/updated results with the full 3 fb^{-1} dataset during LS1.

SHUTDOWN: NO BEAM

Finally, we would like to express our thanks to the CERN accelerator groups for the excellent performance of the LHC in 2012-2013

Available phase-space \rightarrow \pm kinematically harder than K^\pm

$$\Delta A_{CP} = (-0.82 \pm 0.21 \pm 0.11)\% \quad \longrightarrow \quad \Delta A_{CP} = (-0.34 \pm 0.15)\%$$

- The central value is considerably closer to zero than the previous result
- Several factors can contribute to the change
 - larger data sample
 - change in detector calibration (PID and alignment)
 - difference in the analysis technique

Data overlap within the same run period (0.6 fb^{-1})

- In new result, **15%** (K^-K^+) and **14%** ($\pi^-\pi^+$) of events no longer selected
- ~85% of events selected in both old and new processing.
 - Old: $\Delta A_{CP} = (-0.80 \pm 0.23)\%$
 - New: $\Delta A_{CP} = (-0.78 \pm 0.23)\%$
- In new result, **17%** (K^-K^+) and **34%** ($\pi^-\pi^+$) of additional events selected
 - Including additional events: $\Delta A_{CP} = (-0.55 \pm 0.21)\%$.
 - Additional events statistically in agreement with old result.

New data 0.4 fb⁻¹

- Last 0.4 fb⁻¹ recorded by LHCb in 2011 :
 - $\Delta A_{CP} = (-0.28 \pm 0.26)\%$
- Fitting all the 1.0 fb⁻¹ :
 - $\Delta A_{CP} = (-0.45 \pm 0.17)\%$

Effect of constraining D* to primary vertex

- Constraint improves the δm resolution by a factor 2.5.
 - Better background rejection and reducing the statistical uncertainty
- Change in ΔA_{CP} is 0.11%
 - Expected variation (pseudo-experiments): $\pm 0.05\%$

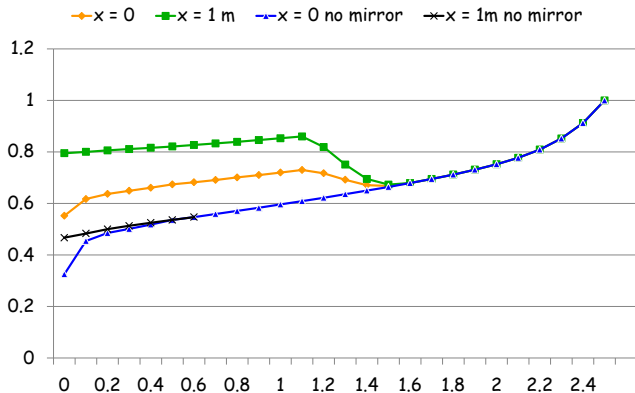

Difference between old and new result understood.
Compatible with statistical fluctuations.

Light yield loss: with mirror and timing cut

Attenuation versus y position ($x = 1$ m means almost no radiation effect)

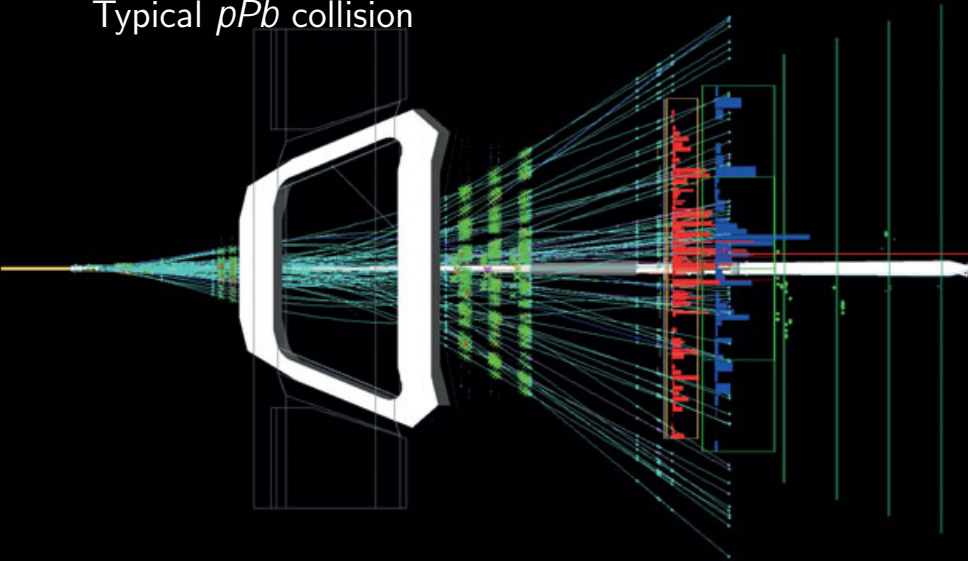

- Effect of mirror and timing cut is to reduce light yield spread for all hits along the 2.5m long fiber

X(3872) angular distribution

- Background subtracted angular distribution (of $\cos\theta_X$).
- Overlaid with the expected angular distribution of $J^{PC} = 1^{++}$ and 2^{-+} X(3872) decay decays.

Typical pPb collision

Λ_b^0 production polarisation

[LHCb-PAPER-2012-057]

Λ_b^0 production polarisation

- Longitudinal polarisation vanishes but, transverse polarisation could be large ($\sim 20\%$) at the LHC [PLB 614 (2005)].
- Non-zero transverse polarisation has consequences for rare decay measurements.
 - Take advantage of production polarisation in $\Lambda_b^0 \rightarrow \Lambda^0$ and $\Lambda_b^0 \rightarrow pK$ decays to determine the photon polarisation, e.g. G. Hiller et al. [[arXiv:hep-ph/0702191](https://arxiv.org/abs/hep-ph/0702191)]
- NB In SM expect R suppressed by $m_s=m_b$ w.r.t. L . Could be enhanced in many NP models.

- $\Lambda_b^0 \rightarrow \Lambda^0 J=\pm$ angular distribution depends on the polarisation factor (P_b) and 4 helicity amplitudes.

- Simplify the angular distribution by integrating over 2 of the 5 angles.
- Polarisation (P_b) and Parity violating asymmetry factor (a_b) consistent with zero:

$$P_b = 0.05 \pm 0.07 \pm 0.02$$
$$a_b = 0.04 \pm 0.17 \pm 0.07$$

→ Rejects HQET prediction of large a_b [PLB 614 (2005)].

$$\propto (1 + P_b a_b \cos \theta)$$

$b\bar{b}$ forward central asymmetry

[LHCb-CONF-2013-001]

$t\bar{t}$ forward-backward and forward-central asymmetries

- Large $t\bar{t}$ A_{FB} seen in $p\bar{p}$ collisions at Tevatron (2.5 from SM).
 - SM contribution arises from interference between LO and NLO $q\bar{q} \rightarrow t\bar{t}$ diagrams.
- At LHC we don't know the direction of the initial partons, measure a forward-central asymmetry:

$$A_{FC} = \frac{N(\Delta|y| > 0) - N(\Delta|y| < 0)}{N(\Delta|y| > 0) + N(\Delta|y| < 0)}$$

- ATLAS and CMS see $A_{FC}^{t\bar{t}}$ close to SM predictions, what about $A_{FC}^{b\bar{b}}$?

$b\bar{b}$ forward-central asymmetry

- Two back-to-back anti- k_T jets ($R = 0.5$) with $p_T > 15 \text{ GeV}/c$, corrected back to the quark level using MC ($(\Delta y) \sim 0.1$).
- b -tag based on 2-, 3 and 4-track displaced vertices (profit from the LHCb trigger).
- Tag b -flavour by requiring that the hardest track is a muon.

Preliminary result:

$$A_{FC}^{b\bar{b}} = (-0.5 \pm 0.5 \pm 0.5)\%$$
